1 Introduction

The work carried out in this task aims at formulating harmonized specifications and at proposing a notation for the lexica and the tagsets, to be contributed by each language group involved in the MULTEXT Project.

MULTEXT's general aim is to develop tools for corpus annotation which contribute to the standardization of this kind of work in an academic and an industrial environment. These tools will be provided with resources from six different languages to ensure their validity. Resources used to feed the tools are, among others, lexical lists for the six languages, containing the necessary information to run the tools. Tools that will use lexica are mainly those which perfom morphological analysis and generation, and lexical lookup tools. MULTEXT proposes to deliver a morphological tool together with basic morphological rules and a number of base form entries, duly coded with respect to the rules. The morphological tool is intended to expand these base forms into word-form lists, with corresponding morphosyntactic information. These word-forms will, in turn, be used for the tagger, providing that a correspondence between the morphosyntactic information and the tags to be used by the tagger is defined. The morphological tool must guarantee extensibility of the MULTEXT tools, as it is thought to be used by end-users to enlarge lexical material treated by the tools. It is also expected that a morphological analysis will be able to perform a "guess" on at least the category of unknown words and, where possible, on morphosyntactic features. Within MULTEXT, therefore, "lexical list" refers to a list of forms with related information: both to base-form lexica, coded in such a way as to feed the morphological tool, and to the word-form lexica, containing relevant information for corpus annotation purposes.

At the first workpackage coordinators' meeting held in Paris, and as also reported in D1.6.1. (September 1994), it was agreed that in view of the urgent need for lexical lists for the creation of the tools, lexical lists of word-forms in a particular format could be supplied already in the first phase, meanwhile leaving for the second phase the development of base-form morphological lexica, input for the morphological tool. These word-form lexical lists were generated from the resources already available at the different sites. Further work will be done in order to ensure the complete mappability between the results of the morphological tool and the formalism proposed for lexical lists.

The present report is mainly devoted to the definition of the information associated with the word-form lists, from now on referred to as "lexical descriptions". We provide here the notation to be used in the lists corresponding to each language to describe a given word-form. Major effort has been devoted to ensure compatibility between the three different types of

information to be associated with a given word: morphological information, morphosyntactic lexical description and TAG label.

The present report is divided into four sections:

- section 2 describes the background considerations taken into account, for the definition of the information and its notation, in these lexical lists;
- section 3 proposes a set of lexical specifications and a common notation for the encoding of the MULTEXT lexical lists of word-forms;
- section 4 considers the relationship between the lexical descriptions and the tags to be used for corpus annotation (this part has to be considered as very preliminary, and having the purpose of highlighting problems and issues arising when trying to arrive at similar ways of defining tagsets for different languages);
- section 5 contains language specific applications of the lexical specifications proposed and still idiosyncratic proposals for the tagsets.

2 Background Considerations

Classification of lexical items relies on the old tradition of Greek and Latin grammar. What is normally referred to as "Parts-of-Speech" distinction for different words is well-known to be a crucial task, but not accurate or universal. Lyons (1981, p.109), for instance, warns the reader about this:

"It is important to realize, however, that the traditional list of ten or so parts of speech is very heteregeneous in composition and reflects, in many of the details of the definitions that accompany it, specific features of the grammatical structure of Greek and Latin that are far from being universal. Furthermore, the definitions themselves are often logically defective. Some of them are circular; and most of them combine inflectional, syntactic and semantic criteria which yield conflicting results when they are applied to a wide range of particular instances in several languages. ... Like most of the definitions in traditional grammar, they rely heavily upon the good sense and tolerance of those who apply and interpret them."

These difficulties in classifying word classes have been the concern of many linguists and greatly affect computational applications, as one cannot expect from machines the sort of "good sense and tolerance" asked for in applying current classifications. On the other hand, the tools MULTEXT is going to develop will be used by humans sharing similar linguistic backgrounds. It is, therefore, imperative that MULTEXT makes these tools user-frendly. It

should not be forgotten that the output of corpus annotation as its main goal, as well as the internal codification used for this purpose, should be easily understandable by the expected end-users of its products. MULTEXT tools will be associated with data for demonstration and validation purposes, but, being public domain tools, one should expect that being allowed to use them for experimentation, end-users will incorporate their own classes and distinctions. It must be ensured that users can take supplied data as guidelines to show the functionalities and behaviour of the tools (the MULTEXT-EAST project evidences the importance of this consideration).

With this aim, MULTEXT proposes to address classification problems by joining forces with the EAGLES initiative (MULTEXT T.A. 1993, p.10) which proposes to address them by highlighting "the area of common ground and some aspects of discrepancy between the different systems for classifying morphological units, in order to provide, after testing with respect to all EC languages, the possibility of elaborating common consensual guidelines for morphosyntactic encoding in lexica and corpora" ("Synopsis and Comparison of Morphosyntactic Phenomena encoded in Lexicons and in Corpora. A Common Proposal and Applications to European Languages", Monachini and Calzolari, Oct. 1994, p.12).

In EAGLES, a bottom-up procedure, looking at existing practices in a large number of lexical and textual projects world-wide (both in lexical specifications and in corpus tagsets), has been followed, thus allowing to highlight the large core of commonalities between lexical and textual large projects with respect to the morphosyntactic phenomena described. The procedure adopted within EAGLES was, in fact:

- to survey a number of encoding practices for morphosyntactic description in lexica (mainly MULTILEX and GENELEX, which in turn, are based on many different lexica for many European languages), and in corpora (i.e. the NERC consensual nucleus of morphosyntactic information encoded by the most well-known existing tagging practices and the preliminary scheme proposed by the EAGLES Corpus working groups) with the aim of finding a consensus from their comparison;
- to work in close cooperation between the groups on linguistic annotation of text corpora and morphosyntactic description in computational lexica, wuth the aim of working out a compatible sets of distinctions;
- to first test the proposal by applying it to the European languages.

Thus, the EAGLES proposal (in the already mentioned EAGLES reports "Synopsis and Comparison of Morphosyntactic Phenomena encoded in Lexicons and in Corpora" and the "Morphosyntactic Annotation", Leech and

Wilson, 1994) – which is also at the basis of, or is mappable to, the lexical and corpus specifications of the LRE projects DELIS, RENOS, CRATER and MECOLB, MLAP project PAROLE, and the French project GRACE – has been the starting point of Task 1.6 within MULTEXT.
The partners have been asked to:

- evaluate if the features and values presented in the tables for each PoS at Level 1, i.e. the recommended features, suit their respective languages and their established practice (an example of the PoS tables used within EAGLES is given below);

NOUN	Type	Gender	Number	Case	Count	Definitness	Inflection
L0	**N O U N**						
L 1	com prop	m f n	sg pl	nom gen dat acc			
L 2					cou mass		
L 2 b		It c Du f(m) Du cont Sp trns Sp notr	It n	Gr voc Gr ind		Da def Da indf Da unmk	Da/Ge weak Da/Ge strg Da/Ge mix

- add features and values needed at the language specific level.

Reports on the evaluation of the EAGLES specifications have been contributed by the partners involved in this MULTEXT task, and comments, suggestions and critical remarks are being taken into account in the EAGLES proposal which is being accordingly revised. MULTEXT Task 1.6. can be seen as the largest contribution, together with DELIS, to the testing, refining and revising of the EAGLES proposal. An example of this interaction was the major revision of the EAGLES proposal which affected the Pronoun/Determiner category proposed, now split into two different categories.

Experience shows that the process of consensus building is a slow process, because of the different interests to be adjusted. Considerations coming from "re-usability" of existing material, as well as from theoretical and application-oriented arguments, have been raised in discussions under this task and should also be taken into account when evaluating its progress and results. Leading ideas to reach final decisions have been described above and will be examined in detail in the following subsections. They can be summarized by the statement of the MULTEXT strong committment to standardization and harmonization of lexical encoding initiatives, now active in Europe with the aim of sharing public domain resources.

2.1 Lexical descriptions and corpus tags

After discussion on several issues, the MULTEXT partners agreed on the necessity of differentiating corpus tags used for the PoS disambiguator, or tagger, from the information which a lexicon can offer. This is because the former is an application-oriented representation of the information described by the latter and depends very much on the tool used. This decision was also in accordance with the orientations given by the EAGLES Lexicon and Corpus working groups (see Monachini and Calzolari, 1994).
Thus the terminology adopted in MULTEXT reflects this separation:

- the term "feature" is preferred when talking about lexical descriptions;
- the terms "tag" and "tagset" are used for the information to be associated with words for automatic corpus annotation.

Hence, it was agreed that two different objects will be produced for each language:

a. a lexicon where morphosyntactic features for each word form are encoded with fine granularity, as close as possible to the recommended EAGLES level-1.

b. a set of tags for the purpose of automatic disambiguation. In practical terms these tags are to reflect broader categories on the basis of the limitations of a statistical tool. This set will be defined and refined upon experimentations with the tagger tool.

In Task 1.6, it was decided – in accordance to the Technical Annex – to begin taking EAGLES recommendations as input for deciding on the basic morphosyntactic information to be associated with the word-forms contained in the lexicon. The MULTEXT application of EAGLES recommendations needed to ensure that the information contained in the so-called Level-1 were significant for most of the languages to be treated. Thus the work under this task may also be considered as a concrete validation of EAGLES work on electronic lexica. The underlying aim of EAGLES is concerned with the re-usability of electronic lexica, and, following this general tendency, MULTEXT lexical descriptions also had to be (as far as possible) independent from the application, aiming at a general description of each language and containing a basic set of shared information. Also, for the sake of "re-usability" of the lexical material supplied, it was judged that the lexical information to be encoded should be as detailed as possible. Thus fine-granularity of the information would allow other users to rearrange categories, when necessary, without much difficulty.

The actual corpus tags we will be using will depend on at least the following:

1. the lexical features, and
2. the capabilities of the MULTEXT tagger to disambiguate between different lexical decriptions, or different types of typical homographies present in different language types.

We can fix (1), but (2) is highly dependent on the tool. That is why we concentrated on (1) in the first phase.

The corpus tags will be developed for each language with a specific application in mind, i.e. that of producing a corpus tagged for part-of-speech (and possibly other morphosyntactic information) by means of automatic disambiguation. The set of corpus tags will, very likely, be revised many times during the course of the project, in order to find an optimal set for each language.

It would be ideal to tag a corpus with the lexical descriptions themselves for each word. However, it is well known that this is well beyond the capabilities of the state-of-the-art tagging techniques.

Corpus tags are, therefore, to be seen as kinds of underspecified lexical tags. There are two reasons why we may want underspecified corpus tags:

1. Experience shows that some distinctions are difficult to get right with a high accuracy.

For example, in some languages, the disambiguation between indicative present and subjunctive present in a corpus is extremely difficult to achieve by automatic means. If some verbs have different forms for the indicative and the subjunctive (e.g. Fr. venir: indic. = viens, subj. = vienne; It. indic. = vieni, subj. = venga), many have the same form (e.g. Fr. manger: indic., subj. and imper. = mange; It. indic. and subj. = ami). In this latter case, disambiguation can only be achieved with very complex parsing of sentences.

Therefore, lexical entries will contain the following detailed and granular information associated with the word-forms

```
mange (manger) Main verb Indicative present, 1st person sing.
mange (manger) Main verb Indicative present, 3rd person sing.
mange (manger) Main verb Subjunctive present, 1st person sing.
mange (manger) Main verb Subjunctive present, 3rd person sing.
mange (manger) Main verb Imperative present, 2nd person sing.

ami   (amare)  Main verb Indicative present,  2nd person sing
ami   (amare)  Main verb Subjunctive present, 1st person sing.
```

```
ami   (amare)  Main verb Subjunctive present, 2nd person sing.
ami   (amare)  Main verb Subjunctive present, 3rd person sing.
```

wheras corpus tags will provide broader categories, collapsing several lexical descriptions.

2. In order to train the tagger, we need statistical tables (based on co-occurrences of tags). If we have a large tagset, we need a very large corpus to train the disambiguator, in order to observe rare co-occurrences. For example, in the proposal for French (see below), there are 249 different lexical descriptions, but only 74 collapsed corpus tags. Experience (Church, Penn Treebank, IBM France, etc.) shows that the tagset should be under 100. Actually the Penn Treebank collapsed many tags compared to the original Brown corpus, and got better results.

Two other observations are of relevance as regards the relation between lexical specifications and corpus tags.

(a) Sometimes tagging classes are in reality different from lexical descriptions. For example, classes for punctuation are needed, certain types of semantic or pragmatic or lexical information can be present in the tags (e.g. the days of the week).

(b) Furthermore, the "collapsing" decisions in TAGS are language dependent, therefore it is not possible to have completely identical tagsets across languages. To illustrate, we can give as an example the differences related to person differentiations in verbal morphology.

In Spanish, first and third person of different tenses have the same spelling:

```
Yo/El cantaba (Imperfect)
Yo/El cantari'a (Conditional)
Yo/El cante (present of subjunctive)
```

Taking into account that the subject in Spanish is not obligatory, and that the tagger cannot know if the preceeding NP is in fact the subject of the verb, there is no way to discriminate between the two forms. Hence a conflating tag is recommended, marked for instance as "non-second-singular" form or as "first- third singular". Also French has homographs for different verbal persons, but these are the first and the second person of some tenses:

```
Je/Tu viens
Je/Tu e'tais
```

The French tag cannot be the same as the Spanish one, but it could be "non-third-singular" or "first-second-singular". Moreover, having two dif-

ferent tags in French for the homograph could be justified, due to the obligatory presence of a lexical subject, as the tagger will be able to disambiguate among them due to the presence of a pronoun in a near context of most of their occurences.

For some languages (e.g. French, English and Italian) a lot of past experience and empirical evidence exists, which can be used to choose a reasonable initial tagset, that can be seen as preliminary and which can be refined later on in the project. For example, for English, the Penn tagset or the BNC are very good candidates. For French, the IBM tagset is a very good start (the French proposal presented in the following is very close to it). For Italian the tagset based on the DMI (Calzolari et al. 1983) is also a good starting point. These tagsets are the result of years of trial-and-error adjustments, and it seems reasonable not to ignore them. All of these tagsets are, moreover, compatible with the EAGLES proposal, i.e. mappable to it.

2.2 Lexical lists: lemmas and inflected word-forms

As stated in the Introduction, MULTEXT will supply a morphological tool which will need some information on lemmas in order to produce the entire set of associated word-forms. A list of word-forms will constitute another lexicon which, as referred in the Technical Annex, constitutes a value in itself. Hence, the lexica supplied by MULTEXT are of two types:

(a) word-forms, containing

Word-form, morphosyntactic information, lemma, TAG

(b) lemmas, containing

Lemma, morphosyntactic information, inflection information

The information and notation of the lemma dictionary is closely related to the morphological tool used and also on the rules implemented within the tool. Due to the fact, mentioned already in the Introduction, that the availability of word-form lists was considered of priority for corpus annotation tool development, we first concentrated on the definition of the word-form lists following EAGLES recommendations for the morphosyntactic annotation to be encoded, as explained in the preceding section. It was possible to define a representation of morphosyntactic information for these word-form lists independent from a morphological tool, in such a way as to ensure that lemma dictionaries and the output of morphological modules (the ones produced for MULTEXT or others) be compatible and easily mappable to such lists. Following current practices for NLP, the notation used should represent information in attribute/value formalisms (as was done also in EAGLES) and should also be self-informative for human inspection and understanding.

Considerations concerning the desirability that these descriptions are able to provide information about language-specific characteristics, where also taken into account. Following these ideas, a notation format was suggested whose main characteristics are:

- attributes are marked by positions;
- values are represented by a single character;
- a special marker reflects the non applicability of a given attribute.

These characteristics make the proposed lexical description notation (see section 3.1 for more details) synonymous with attribute/value pairs used in current unification formalisms. The next sections introduce such formalism and the information to be encoded.

3 MULTEXT lexical specifications and notation

3.1 Notation

The notation format proposed to represent lexical descriptions consists of linear strings of characters representing the morphosyntactic information to be associated with word-forms. The string is constructed following the philosophy of the Intermediate Format proposed in the EAGLES Corpus proposal (Leech and Wilson, 1994), i.e. of having agreed symbols in predefined and fixed positions: the positions of a string of characters are numbered 0, 1,2, etc. in the following way:

a. the agreed character at position 0 encodes part-of-speech;
b. each character at position 1, 2, n, encodes the value of one attribute (person, gender, number, etc.);
c. if an attribute does not apply, the corresponding position in the string contains a special marker, in our case '–' (hyphen).

```
Example: Ncms- (noun,common,masculine,singular,nocase)
```

This notation adopts the EAGLES Intermediate Format with a small revision: the Intermediate Format encodes information by means of digits, while in MULTEXT characters of a mnemonic nature are preferred.

It is worth noting here that this representation is proposed for word-form lists which will be used for a specific application, i.e. corpus annotation. We have foreseen these lexical descriptions as containing a full description of lexical items. As noted above, the sets of tags, to be used properly for automatic corpus annotation tools, are expected to contain less information.

These lexical descriptions can be seen as notational variants of the feature-based notation in the form of attribute-value pairs. In fact, the string notation proposed, e.g.

```
Ex.: Ncms- (noun,common,masculine,singular,nocase)
```

is completely synonymous to a feature-structure representation:

```
Ex.: {cat=noun, type=common, gender=masculine, number=singular, case=none}
```

or

```
{cat=noun, type=common, gender=masculine, number=singular}
```

The above feature structures are often also represented as follows:

```
+-                      -+
| Cat:    Noun           |
| Type:   common         |
| Gender: masculine      |
| Number: singular       |
+-                      -+
```

Formal characteristics relevant for our applications have been kept. Use of position in the string to encode attributes makes no restrictions on the set of characters to be used as values. It could then be inferred that, if we wanted to keep the formal characteristic of order independent notation, we would have to make sure that the characters meant to represent attribute-values are not ambiguous. As attributes and values are linked by positional criteria, the need of a special marker for void attribute-value pairs is evident if we want to keep descriptions coherent. Thus, the "Ncms-" style can be viewed as a short-hand notation convenient for some users and straightforwardly mappable to the information used in unification-based attribute-value pairs formalisms.

When comparing MULTEXT lexical description representation format with other notations one must keep in mind that they are intended to describe word-forms, and are used in very large lexical lists which contain word-forms. It seems to us relevant to comment on this point because, although it can be justified (and we will do so below) that the same formal operations can be declared in both styles, there is little evidence for justifying the need of operations such as negation and disjunction of features and values when applying them to tagged word-forms as a result of corpus annotation.

3.1.1 The use of '–' ('not-applicable')

We call this marker 'not-applicable'[1], and, as stated above, its function is just to keep the relationship established between attributes and values. It might be used for the following cases (it has been proposed to use the 'not-applicable' marker in order to encode the case of a not-applicable feature for a particular language. However this decision is still under discussion due to the facts reported in section "Comparison of attributes/values used by languages"):

a. not applicable given a particular combination of attributes/values, i.e. although the attribute applies to the category in a given language, it does not apply to a particular subclass of the category.

b. not applicable to a particular lexical item, although the attribute applies to the rest of its paradigm.

Example: in the description of pronouns, for personal pronouns the grammatical person is to be encoded, but for demonstrative pronouns it is avoided; in this case '–' is applied following (a). On the other hand, gender cannot be informative for some personal pronouns, but it is still relevant for other personal pronouns; the application of '–' follows (b):

```
Pd-ms     "Este"     Pronoun, demonstrative, masculine, singular.
Pp1-s     "Yo"       Pronoun, personal, first, singular.
Pp1mp     "Nosotros" Pronoun, personal, first, masculine, plural.
Pp1fp     "Nosotras" Pronoun, personal, first, feminine, plural.
```

Their uses are clearly not equivalent, but there would only be meaningful differences would occur in highly typed theories of lexical description. For illustrating this point let'us have the following type system for pronouns:

[1]This section and the following are still under discussion and present proposals coming from different partners which still need to be revised and/or refined.

TYPES	SUBTYPES	ATTRIBUTES	VALUES
Pronoun		gender	masculine
			feminine
		number	singular
			plural
	Demonstrative		
	Personal	person	1
			2
			3

For this system, gender and number attributes belong to the set of features which describe all pronouns. Person will only belong to the set of features which describe personal pronouns – in addition to gender and to number. Applied to this type system, case (a) would mean that the attribute-value pair does not belong to the set of features which describe a subtype, while (b) would mean indeterminacy of a given word-form (which could be expressed as a disjunction of all the values for the particular attribute or leaving a void for the value, being open to unification; this choice mainly depends on the purpose of the description, e.g. syntactic parsing).
Different representations will result: 'este' description corresponds to case (a), and 'yo' description corresponds to case (b) (subtypes are represented 'dem' and 'pers'):

```
|phon                este|
|cat     |gender    masc||
|   'dem'|number    sing||

|phon                yo   |
|cat      |gender    []  ||
|   'pers'|number    sing||
|         |person    1   ||
```

In simpler flat type systems where distinctions are made only for the generic type "pronoun", both cases a. and b. will be treated by unification mechanisms in the same way.

From the conversion point of view, we have to be concerned with the output of the MULTEXT morphological tool, as it will be the source of word-form lexical lists. The Mmorph tool does not incorporate a highly hierarchical typing system and thus no problems are expected in converting Mmorph output into lexical descriptions of the proposed format, if desired. The results from applying the Mmorph tool will probably (it strongly depends on

implementation strategies) be the following:

1. a non present attribute in the description attached to the word-form;
2. a disjunction expression, i.e. {gender=masc|fem};
3. encoded as a third possible value, i.e. {gender=none}.

The simplest case for converting would be the third one, as then automatic non-intelligent conversion is possible. In the first two cases the conversion routine will have to make some inferences on type declarations. It is also expected, that when converting from other lexical sources, special conversion routines will have to be used. As seen above, the conversion from "Ncms" lexical description notation into other unification based format will only be difficult if the target formalism is a highly typed system. If this is not the case, the presence of the "not-applicable" marker will have to be converted into a special value or into nothing, leaving it open. For conversion into highly typed system it might be useful to have cases (a) and (b) marked by different characters, in order to guide an intelligent conversion routine to the desired results.

3.1.2 Mapping of lexical descriptions onto corpus tags

The tags (see the examples below) used to exemplify issues and problems to be dealt with in the mapping between lexical descriptions and corpus tags, come from the tagsets proposed in the language-specific applications of four of the MULTEXT partners. These tagsets (containing dfferences among them, because constructed on the basis of tagging practices already used by the partners) should be considered as a preliminary proposal to be discussed for harmozation and refined after experimentations on the MULTEXT tagger.

Mapping of these lexical descriptions into corpus tags has also been taken into account. It is also considered desirable to see whether under-informative corpus tags can be directly mappable to the lexical descriptions each one subsumes.

Decisions about corpus tags are language dependent. The information to be encoded depends on the ability of a given tool to disambiguate between different potential lexical descriptions for a given word-form. We have already mentioned the key concepts to be applied for defining sets of corpus tags in the preceding sections. Therefore one can first assume that the mapping from lexical descriptions onto corpus tags can be done with conversion tables which relate two different items: corpus tags and lexical descriptions. These tables are likely to be modified many times in the course of the project, based on experimentation with the disambiguation tool.

An example of such mappings is:

```
Lex.spec. TAG   Definition

Pp1msa-   P1S   Personal pronoun, first person, masc. sing. accusative
Px1msa-   P1S   Reflexive pronoun, first person, masc. sing. accusative
Pp1fsa-   P1S   Personal pronoun, first person, fem. sing. accusative
Px1fsa-   P1S   Reflexive pronoun, first person, fem. sing. accusative
Pp1msd-   P1S   Personal pronoun, first person, masc. sing. dative
Px1msd-   P1S   Reflexive pronoun, first person, masc. sing, dative
Pp1fsd-   P1S   Personal pronoun, first person, fem. sing., dative
Px1fsd-   P1S   Reflexive pronoun, first person, fem. sing., dative
```

All these lexical descriptions correspond to the Spanish form "me". For this word-form the tags P1S – which conflates all the possible lexical descriptions – has been decided on the basis of the assumption that an automatic tool would have disambiguation problems in assigning the correct analysis among all the lexical descriptions. The correct analyis of this word-form would require syntactic analysis.

The mapping from the lexical descriptions to the corpus tags should be applicative, that is, "each lexical description should map to one and only one corpus tag, while it is not possible to do the reverse" due to the limitations of current tagging techniques. The situation where corpus tags are more precise than a lexical description (i.e. one lexical tag corresponds to more than one corpus tag) should be, in principle, avoided.

In order to avoid redundancy in the conversion tables and to make tag optimization work easier, it has been proposed to study the possibility of having intermediate representations which prepare the conflation of information and which facilitate automatic mapping from lexical descriptions onto tags. This intermediate internal notation makes use of "regular expressions" which incorporate operators in order to sum up the information referred by different lexical descriptions and conflated in a given tag. For the example given above, the resulting regular expression may incorporate two operators: "match any" (.), "list" ([]) – other possible operators proposed are "disjunction" | and negation ~

```
P[px]1.s[ad]-     P1S
```

However, the application of such regular expressions is still being studied as its use conveys some requirements on the conflation of lexical descriptions and on the construction of corpus tags. An example will illustrate the issues to be taken into account. For Spanish, first and third person of some

tenses are homographs. This can be taken into account when conflating information:

Verbal paradigm	regular exp.	TAG
cantaba, comi'a, veni'a	Vmii[13]s-	VMIIS
cantari'a, comeri'a, vendri'a	Vmcs[13]s-	VMCSS
cante, coma, venga	Vmsp[13]s-	VMSPS
cantara, comiera, viniera	Vmsi[13]s-	VMSIS

For Italian, the conflation of information on homographs also in the verbal paradigm may cause problems to the applicative principle mentioned above:

Verbal paradigm	lex.descr.	regular exp.	TAG
premiate	Vmip2p- Vmmp2p- Vmsp2p- Vmps-pf	Vm([ims]p2p-)|(ps-pf)	VMP2IMCPP
leggete	Vmip2p- Vmmp2p-	Vm[im]p2p-	VMP2IMP
leggiate	Vmsp2p-	Vmsp2p-	VP2CP
lette	Vmps-pf	Vmps-ps	VFPPR

As can be seen, if we use tags such as the ones above which are based on the principle "one graphical form – one tag", there is a violation of the applicative principle, i.e. the same lexical description will correspond to two different tags, because of different conflation clusters.

In general, it is observed that the use of operators in regular expressions results in a form of marking the information which is not going to be expressed in the corpus tag. Thus, tags would have to contain less information than the regular expression and hence than the lexical description.

Another issue to be considered is the following. Having tags with little lexical information, as in the following French example, may lead to another problematic issue in cases where such regular expressions are also used in helping to recover all possible lexical information from a given "under-specified" corpus tag. The mapping from the regular expression onto lexical descriptions will also have to take into account the word-form in order to reject possible descriptions which do not correspond to the tagged word-forms. Below are some examples from the proposed verbal tags and regular expressions:

TAG	Regular expression	Lexical descriptions	Possible word-forms

VM1P	Vm[iscm][pifs]1p--	Vmip1p--	venons
		Vmii1p--	venions
		Vmif1p--	viendrons
		...	....

Let us consider that the word "venons" is tagged as "VM1P". If we want to know which are the lexical description to which the tag can be referring to, the explosion of the information contained in the regular expression will also give lexical descriptions which do not correspond to the word "venons", but to other words. Regular expressions can only map a given tag for a word-form into all possible lexical descriptions for such a word-form if the information conflated only reflects ambiguities due to homography. Only with this criterion for defining tags, all the possible lexical descriptions subsumed by the corpus tag and expressed in the regular expressions will be true of a given tagged word.

If the criterion for conflating information is limited to homograph ambiguities, we see – as in the following example – that all possible lexical descriptions expanded from the regular expression are true of a given word-form.

TAG	Regular expression	Lexical descriptions	Possible word-forms
VSXICP	Vm(sp.s)|(ip2s)-	Vmip2s-	ami
		Vmsp1s-	ami
		Vmsp2s-	ami
		Vmsp3s-	ami

As mentioned in the section "Comparison of Attributes/values used by languages", the application of the proposed operators in regular expressions for avoiding redundancy, in some cases, is not needed if lexical expressions already encode the possibility of having, for a given word-form, more than one possible lexical description. This is the case with the proposed values "common" for gender, "invariant" for number (in Italian), or "object" for case (in French pronouns).

Almost all the languages treated in MULTEXT have nouns, adjectives, determiners (among others) which have the same word-form both for feminine and masculine agreement. The Italian group has proposed a value for gender named "common" which avoids having to write two different entries with the same word-form, but with different lexical descriptions. In fact, this use of a special value advances the possible use of proposed operators in the regular expression.

word-form	lexical description	regular expression	TAG
insegnante	Nccs-	Nccs-	NNS

could also be expressed as:

word-form	lexical description	regular expression	TAG
insegnante	Ncms-	Nc[mf]s- or Nc.s-	NNS
	Ncfs-	or Nc(m|f)s	

The need, as well as the consequences, for the mapping between lexical descriptions and corpus tags, of the regular expressions must still be regulated. It should be noted that regular expressions can be regarded as a convenient way to map the lexical descriptions to the corpus tags since, in many cases, the information in the lexicon is more precise than the information we can/want to have in the corpus tag set. Such a mapping still seems very interesting because there are many corpus tag systems, even for the same language, which makes it extremely difficult to relate the one to the other. Regular expressions could act as a common reference for the different systems to make comparison easy. Besides, regular expressions could make translations between the lexical description and corpus tags easier and enable the automatic generation of conversion tables.

3.1.3 Attribute/value tables

The categories listed below with the relevant attributes and values are based on EAGLES documents and are the results of a first testing based on a proposal made by Veronis et al. 1994 for lexical specifications in MULTEXT.

As it has already been mentioned in the section "Background considerations" that propose features for describing lexical items of different languages aiming at defining a set which can be said "common" for all of them is a complex task. The underlying philosophy for this task has then be to lead different groups into a pragmatic solution where the concept of an "harmonized" set of features could be reached.

The groups have first worked out their lexical descriptions taking as input EAGLES and Veronis et al. (1994) documents. The very general criterion was to encode those proposed features which were considered relevant for the language in question. Therefore MULTEXT also followed EAGLES bottom-up methodology in trying to define extensively the features "used" in the lexical descriptions for each group language, as this procedure will make evident the features commonly used. After this phase, whose result can now be seen in the section "Comparison of attribute/values used by the groups", a new phase is envisaged as to accomodate language-specific considerations into a general model to be used by MULTEXT. This accomodation must take into account extensibility to other languages and also application motivated arguments, as well as internal coherence. For this new phase more specific criteria would be desirable with respect the addition of new features

to the EAGLES Level-1 set. The aimed result is a "harmonized" set of features which properly describe lexical items of the different languages.

Following the general aim of the project, these harmonized specifications – and the related resources – will contribute to the standarization of the corpus annotation work. They are supposed to serve as a user oriented additional characteristic of our tool package in the sense that end-users will have a common ground for inspecting and understanding the resources and tool results independently to a large extent of the language. This common set of features will also be a common ground to perform comparisons of different annotation tool results, because, as mentioned in the previous section, the existence of many lexical description systems is causing nowadays a problem for comparing results.

Therefore the categories and features listed below are the common reference for the work done by the different groups. Further discussion on this first proposal is to be found in the section "Comparison of the attributes/values used by the groups" which is in turn to define criteria for changing this first proposal.

Tables of categories

Part-of-Speech	Code	
Noun	N	
Verb	V	
Adjective	A	
Pronoun	P	
Determiner	D	(for those who do not have a separate category
Article	T	for Articles, these are included in Determiner)
Adverb	R	
Adposition	S	
Conjunction	C	
Numeral	M	
Interjection	I	
Unique	U	
Residual	X	
Abbreviation	Y	

Each character at positions 1, 2, etc. encodes the value of one attribute (person, gender, number, etc.), according to the tables

given below.

3.1.4 Comparison of Attribute/value features used by the groups

The following tables reflect the attributes and values used for lexical description in MULTEXT. They take into account input supplied by different groups which the reader can find further detailed in specific language application annexes (see section 5). It is worth noting that the tables reflect both features used by five groups using lexical descriptions as proposed in previous versions of this document and also features for Dutch resulting from morphological generation with the "mmorph" tool. The comparison is certainly of help in order to have a clear picture of the level of consensus reached with respect to harmonization when elaborating lexical lists. It has already been mentioned in previous sections that the project is working towards defining criteria for the application of EAGLES guidelines on standardization of lexical resources for easy re-usability.

Looking at the tables below some very general issues arise with respect to the application criteria of the general tables to the particular languages and the interpretation of the general guidelines. Until now groups have been working on the assumption that they must encode recommended Level-1 EAGLES features if they are relevant to their languages. The possibility of adding new values and new attribute/value pairs was also foreseen if recommended features were not enough to describe lexical items with fine-granularity of lexical descriptions. It was also found useful in view of supplying lexical material to be used by other tools than the MULTEXT ones. This openness has led to a number of incoherencies with respect to application criteria which we summarize in the points below. A decision with respect to general criteria for application must be reached in the next phase. Hence, here the issues concerning harmonization which arise from comparing application sections follow.

There is an unbalanced treatment of features considered as "general" for the different categories. The presence of a particular attribute seems to be mainly justified for two reasons:

– representative in most of the studied languages;
– linguistic tradition.

We see in the comparative tables that a particular language is allowed to add a new attribute because of its relevance for the lexical description of a given category (i.e. when the language items belonging to that category are inflected or marked with respect to it). The most evident case is the proposal made in order to encode Possessor-gender (among other features) for Pronouns and Determiners. It is obvious that this feature cannot be used by languages which do not have different forms regarding this partic-

ular distinction.

On the other hand, note that "case" as a feature recommended as "general" for describing Nouns, Adjectives, Pronouns, Determiners, Articles and Numerals, is in fact used only for Pronouns by most of the languages, and only German can apply it for the rest of the categories.

What we mean by "unbalanced treatment" has to do with the fact that features being used by just a few languages, or even just one, receive different treatment when considering them "general" or "language specific".

Also arising from the possibility of adding language specific attributes and values where relevant for a given description, the procedure followed in this task has shown that it has not been easy to reach a consensus in order to harmonize a number of specific features and values considered by a given language. One of cases of such proliferation of features is seen, in fact, when considering the comparative table for Determiners. One of the groups suggests having language specific types to refer to "definite article" and "indefinite article", while other groups prefer to have a general type "article" and other attributes, i.e. Quantification or Definiteness to encode this distinction at a lower level. The particular features suggested by the groups which, in our opinion, could be adapted to the EAGLES model will be discussed during the next phase.

Because of this openness with respect to adding attibutes and values, we would like to point out the case for the values "common" and "invariant" added by the Italian descriptions to all nominal inflected categories for the attributes "gender" and "number" respectively (where a disjunction of values could be used instead). It is a fact that most of the languages could easily adopt this value for the forms which are identical for masculine/feminine, singular/plural agreement features, but this issue has certainly to be clarified and further discussed. Probably a decision with respect to the "fine granularity" of lexical descriptions should be devised. In fact there is another example in another category of the same strategy, that is to conflate in a new value for a given attribute a homography which causes explosion of entries. The French group has suggested conflating accusative/dative values for pronominal case into "object" as a generic value. The new division proposed would also apply to other romance languages but it might compromise the "fine granularity" tendency the project aimed at for lexical descriptions.

There can also be observed a certain confrontation of two different traditions when some groups propose to add a new attribute to characterise an element while others propose to add a new value to label a new class under a general, already available attribute such as "type". To add a new attribute would

correspond to the unification based grammar practice, and a label for a class would correspond to the so called "taxonomic" theories. We see an example of this confrontation in the proposal of having an attribute/value "wh" for marking relative particles in different categories: pronouns, determiners, adverbs. EAGLES level-1 seems to prefer separating relatives with a different value for the attribute "type" of pronouns and determiners. Marking as an additional feature the relative characteristics of a given pronominal would help for instance to specifically characterise items such as the English "whose" or Spanish "cuyo, cuya, cuyos, cuyas" which are normally described as Possessive relative pronouns. Under the current classification a decision must be made either to put them under the Possessive or the Relative value of the attribute "type". It has also to be mentioned that no special treatment can be made for relative adverbs which are not taken as a separate class under Adverb type in the EAGLES proposal. Thus, from the comparison made, it is worth mentioning that a new attribute "wh" for adverbs or, as suggested by the German group, a new value for interrogative – and also for relatives – adverbs should be devised.

As we have seen, the EAGLES recommendations lack in some cases the desired fine-grained distinctions which groups working in MULTEXT consider desirable for our applications. Another example of this case is raised by German and English. The groups dealing with these languages – and it could also be applied to the rest of the languages – have suggested a specific value for comparative conjunctions. This addition seems reasonable under the argument that it is an important feature with respect to distributional criteria and can be of great importance for tagging purposes. Again, some guidelines must be defined for considering the addition of features not contained in EAGLES level-1, but it is worth noting that several of the features added for language specific reasons could be considered as applicable to the rest of the languages.

We recommend a new round of discussions on the new features suggested in specific language applications to see whether they can be of use in our concrete application and applicable to the rest of the languages. Once this discussion has led to conclusions, the approved features must be included in the general model. Besides linguistic considerations, having an agreed set of general features is of great concern for the chosen notation style in lexical descriptions. There must be regulations with respect to the encoding of language specific attributes by the other groups or on the ways of differentiating them from those of the general model. This is especially relevant if general conversion routines are to be developed. And because of theroretical coherence, the treatment given to these features must take into account the above mentioned "unbalanced treatment of features". Some other doubts remain in connection with theoretical coherence and the applied nature of

the lexica to be supplied. We would only mention one of them to illustrate the kind of issues which must be taken into account in the next phase. It has to do with agreement features of person, number and gender. Are they to be encoded with respect to grammatical agreement or with respect to semantic differentiations. As it is now, following EAGLES recommendations, it seems as if only semantic considerations are taken into account, i.e. Possessive-person of determiners is taken as the "possessor person" for most of the languages which in fact does not trigger agreement.

A decision must be taken with respect to these cases and more specific guidelines must be established for further development of lexical descriptions. It seems from the comparison made that the general criteria "relevant for your language" is not enough. New guidelines must also take the application side into account.

Comparison tables

```
Abbreviations used:
    P   = Position (starts with 0 for encoding PoS values)
    ATT = Attribute name
    VAL = Value
    C   = Code

    x   = value marked by a given group (any character other than x
          means that a given 'language group' codes, in their
          application, the relevant value with that character, not using
          the agreed one).
          The column of characters is left empty in correspondence of
          language specific attributes/values of
          Dutch: they  are attested, in fact, among the set of attributes
          and values for Dutch implementation of Mmorph, where they are
          not represented by means of single codes.

4 Comments on labels for corpus tags

Current enconding practices use widely different naming conventions for corpus tags. We can find different sets of labels also for the same language – for example SUBSMS, SBMS, NCMS, Nms, etc. can represent "Common noun, masc. sing." in different systems for the very same language.

It has been found, as already mentioned, that corpus tags are strongly committed to the tool and to the language. Therefore, each language will have its own set based on different considerations. However it was considered helpful to suggest some naming conventions for the sake of harmonization. The following is an attempt done by the French partners to give simple

general guidelines for achieving a coherent naming convention within the project.

1. Corpus tags should be all upper case, in order to distinguish them from lexical descriptions.
2. Part-of-Speech should be encoded in a single character by the first letter using the same convention as the lexical categories used for lexical descriptions.
3. If possible, each of the characters after the first one should encode one by one the attribute-values using the same letter as in the lexical descriptions but upper case.
4. In case of ambiguity, or merging of values, one should use new characters, not already in the set of possible values for that attribute.

This is not a formal system, and may lead to ambiguities. In order to have a final set of tags a thourough testing must be performed as experimentation is going to show the behaviour of a given set. Also considerations coming from the decision taken with respect to the need and usefulness of special devices for automatic conversion are expected to have some impact in the concrete tags given for a language. Thus, the tags proposed by each group for the time being must be considered temptative until the end of the experimentation phase.

5 Language specific applications

5.1 Application to Italian

In this section the MULTEXT set of lexicon specifications is applied to Italian (Calzolari and Monachini 1994). The language-specific values added for Italian are highligthed with the code 'l-spec'.

Furthermore, a preliminary tagset for Italian is proposed. This is based on the tagset used by our tagger, but also takes into account the criteria expressed above for the construction of the tagset, and the results of a first cycle of experimentations on the MULTEXT tagger.
A table containing the the translation of the tag into the regular expression and its definition is presented, i.e.

```
        TAG       Reg.expr. Definition

        NMS       Ncms-     Common noun, masc.sing.
```

A table displaying the mapping between lexicon specifications and corpus tags is provided, along with an examplification.

```
5.1.1 Nouns (N)
---------------

5.1.1.1 Lexicon
```

Attribute	Value	Example	Code
Type	common	libro	c
	proper	Gianni	p
Gender	masculine	uomo	m
	feminine	donna	f
l-spec	common	insegnante	c
Number	singular	uomini	s
	plural	donne	p
l-spec	invariant	attivita'	n
Case	(n.a.)	(n.a.)	-

5.1.1.2 Corpus

Tag	Regular expression	Definition
NMS	Ncms-	Common noun, masc. sing.
NMP	Ncmp-	Common noun, masc. plur.
NMN	Ncmn-	Common noun, masc. invar.
NFS	Ncfs-	Common noun, fem. sing.
NFP	Ncfp-	Common noun, fem. plur.
NFN	Ncfn-	Common noun, fem. invar.
NNS	Nccs-	Common noun, comm. sing.
NNP	Nccp-	Common noun, comm. plur.
NNN	Nccn-	Common noun, comm. invar.
NP	Np..-	Proper noun

5.1.1.3 Combinations

Lexicon	Corpus	Example
Ncms-	NMS	libro
Ncmp-	NMP	libri
Ncmn-	NMN	re, caffe' (il/i)
Ncfs-	NFS	casa
Ncfp-	NFP	case
Ncfn-	NFN	attivita' (la/le)
Nccs-	NNS	insegnante (un/una)
Nccp-	NNP	insegnanti (gli/le)
Nccn-	NNN	sosia (il/la, i/le)
Np..-	NP	Mario, Maria, Borboni

5.1.1.4 Some obsevations for the corpus tagset

The idea of the French group to tag Proper Nouns simply with NP (collapsing the information on gender and number) seems the best solution.

5.1.2 Verb (V)

5.1.2.1 Lexicon

Attribute	Value	Example	Code
Type	main	amare	m
	auxiliary	avere	a
Mood/VForm	indicative	amo	i
	subjunctive	ami	s
	imperative	ama	m
	conditional	amerei	c
	infinitive	amare	n
	participle	amato	p
	gerund	amando	g
Tense	present	amo	p
	imperfect	amavo	i
	future	amero'	f
	past	amai	s
Person	first	amo	1
	second	ami	2
	third	ama	3
Number	singular	amo	s
	plural	amiamo	p
Gender	masculine	amato	m
	feminine	amata	f
l-spec	common	amante	c

5.1.2.4 Some observations for corpus tagset

An observation concerns the special marking for the auxiliaries: the taggers are in general not able to disambiguate the cases in which the auxiliaries are used as full verbs ("io ho un cane" , "i bambini sono nel prato") from the cases when they are auxiliaries. The distinction of the auxiliaries is used only in order to isolate 'avere' and 'essere' from the other verbs.

For verbs, two different sets of tags are proposed, the first more fine-grained for more accurate distinctions and the latter more coarse-grained, which follows the approach proposed by the French group.

The collapsing proposed by the French group of Moods and Tenses, if considered wrt to the performances of our tagger, appears restrictive: for many unambiguous tenses and moods, the Italian tagger is able to formulate the correct analysis (e.g. conditional, subjunctive imperfect, indicative past etc.) and these distinctions are, in our opinion, worth being maintained. It has to be noticed that the ambiguities between verb forms depend also on different lexical verbs.

In Italian, the major ambiguities concerns the 2nd sing and plur of the present indicative and imperative, ama-amate; leggi-leggete. However, this is again not a general rule.

Another very common ambiguity is between the 2nd pers. of the indicative and the 1st, 2nd, 3rd person of the present subjunctive. Therefore not always it is possible to decide unambiguosly on the person.

Some more frequent typical homographies in Italian are listed below:

```
VP1ICP   amiamo
VP2IMP   leggete
VP2IMPP  amate
VP2IMCPP premiate
VP2ICR   amaste
VS^3CI   amassi
VSXCP    legga
VAY^2IP  sono
VSXICP   ami
VS2IMP   leggi
VS^1IMP  ama
VS^1IMP  ama
```

In the design of corpus tagsets for verbs careful attention should be given to the enclitic phenomenon: at present our tagger is able to recognize the presence of the clitics which is signalled by the addition of the mark "+E" (plus clitic) to the regular verb tag.

5.1.3.4 Observations

The comparative Degree applies only to a close set of adjectives (e.g. maggiore, migliore, etc). All other adjectives form their comparatives with "piu'" + adjective (e.g., piu' forte). Superlative is also an analytical form (il piu' forte), but can be also synthetically formed: grandissimo, massimo.

5.1.4.4 Observations

For pronouns, the strategy of proposing two different tagsets, the one more collapsed and the other more fine-grained is followed.

As far as the pronominal paradigm is concerned, Case is not encoded at present in our DMI (Calzolari et al. 1983).
Personal pronouns are not lemmatized: 'gli' is not considered the dative form of the base pronoun 'egli' (he), but constitutes a separate entry.

The Italian pronominal paradigm is the following:

'forme toniche' (strong forms): subj (io, egli), compl (me, lui)

ama me / da' a me -- dir-obj/prep-obj --
(he loves me / he gives to me)

ama lui / da' a lui -- dir-obj/prep-obj --
(she loves him / she gives to him)

'forme atone' (weak forms): - compl (mi, gli/lo)

mi da' / mi ama -- ind-obj/dir-obj --
(he gives me / he loves me)
gli da' -- ind-obj --
(he gives him)
lo ama -- dir-obj --
(she loves him)

This paradigm can be mapped on the Case system proposed by the French group, in the following way:

io, egli	= subj	= nom
mi/me	= dir-obj/ind-obj/prep-obj	= obj -] acc, dat, prep+obl
lui	= dir-obj/prep-obj	= obj -] acc, prep+obl
gli	= ind-obj	= dat
lo	= dir-obj	= acc

5.1.5.4 Combinations

On the basis of the strategy adopted for Pronouns, also for Determiners two tagsets are proposed.

5.1.6 Articles (T)

5.1.6.1. Lexicon

Attribute	Value	Example	Code
Type	definite	il	d
	indefinite	un	i
Gender	masculine	il	m
	feminine	la	f
l-spec	common	l’	c
Number	singular	la	s
	plural	le	p
Case	(n.a.)	(n.a.)	-

5.1.6.2. Corpus

Tag	Reg.Expr.	Definition
RMS	Tdms-	Article, definite, masc.sing.
RMP	Tdmp-	Article, definite, masc.plur.
RFS	Tdfs-	Article, definite, femm.sing.
RFP	Tdfp-	Article, definite, femm.plur.
RNS	Tdcs-	Article, definite, comm.sing.
RIMS	Tims-	Article, indefinite, masc.sing.
RIFS	Tifs-	Article, indefinite, femm.sing.

5.1.6.3. Combinations

Lexicon	Corpus	Example
Tdms-	RMS	il, lo
Tdmp-	RMP	i, gli
Tdfs-	RFS	la
Tdfp-	RFP	le
Tdcs-	RNS	l' (amico/a)
Tims-	RIMS	un, uno
Tifs-	RIFS	una, un'

5.1.7 Adverbs (R)

5.1.7.1 Lexicon

Attribute	Value	Example	Code
Type	-	-	-
Degree	positive	bene	p
	superlative	benissimo	s

5.1.7.2 Corpus

Tag	Regular Expression	Definition
B	R-p	Adverb positive
BS	R-s	Adverb superaltive

5.1.7.3 Combinations

Lexicon	Corpus	Example
R-p	B	fortemente
R-s	BS	fortissimamente

5.1.7.4. Observations

The feature Type is not encoded in the Italian lexicon.

5.1.8. Adposition (S)

5.1.8.1. Lexicon

Attribute	Value	Example	Code	
Type	preposition	di, a, da	p	
Formation	simple	di	s	
	compound	dello	c	
Gender	masculine	dello	m	This attribute and values
	feminine	alla	f	have been added
l-spec	common	dell’	c	
Number	singular	al	s	This attribute and values

	plural	ai	p have been added

5.1.8.2 Corpus

Tag	Regular Expression	Definition
E	Sp-	Preposition simple
EA	Spc..	Preposition compound

5.1.8.3 Combinations

Lexicon	Corpus	Example
Sp	E	di
Spcfs	EA	della
Spcfp	EA	delle
Spcms	EA	del, dello
Spcmp	EA	dei, degli
Spccn	EA	dell’

5.1.8.4 Observations

The Italian policy for encoding fused prepositions foresees to attach the morphological information of the article to the preposition tag.

5.1.9 Conjunctions (C)

5.1.9.1. Lexicon

Attribute	Value	Example	Code
Type	coordinat.	e	c
	subordinat.	perche’	s

5.1.9.2 Corpus

Tag	Regular Expression	Definition
CC	Cc	Coordinative conjunction
CS	Cs	Subordinative conjunction

5.1.9.3 Combinations

Lexicon	Corpus	Example
Cc	CC	ma
Cs	CS	perche'

5.1.10 Numerals (M)

5.1.10.1. Lexicon

Attribute	Value	Example	Code
Type	cardinal	cento	c
	ordinal	primo	o
Gender	masculine	primo	m
	feminine	prima	f
Number	singular	secondo	s
	plural	secondi	p
Case	(n.a.)	(n.a.)	-

6.4.10.2 Corpus

Tag	Regular Expression	Definition
NMS	M.ms-	Numeral, masc.sing.
NFS	M.fs-	Numeral, femm.sing.
NMP	M.mp-	Numeral, masc.plur.
NFP	M.fp-	Numeral, femm.plur.
N	Mc---	Numeral cardinal

5.1.10.3 Combinations

Lexicon	Corpus	
M.ms-	NMS	primo
M.fs-	NFS	prima
M.mp-	NMP	primi
M.fp-	NFP	prime
Mc---	N	zero, cento

5.1.11 Interjection (I)

5.1.11.1. Corpus

Tag	Reg. Expr.	Definition
I	I	Interjection

5.1.11.2. Combinations

Lexicon	Corpus	Example
I	I	oh

5.1.12 Unique membership class (U)

None

5.1.13. Residual (X)

5.1.13.2 Corpus

Tag	Regular Expression	Definition
NY	???	"Guessed" Noun
AY	???	"Guessed" Adjective

5.1.13.3 Combinations

Lexicon	Corpus	Example
???	NY	bit
???	AY	computerizzato

5.1.13.4 Observations

At corpus level, we have the tag SY which is used to mark symbols, letters, acronyms, foreign words, toponyms etc., in general unknown words, for which a "guess" is provided.

5.1.13 Punctuation

Tag	Example
punct	.,;:?! etc.

========= ============================

5.2 Application to German

The application of the MULTEXT encoding scheme to German has been carried out by the German group (Steiner and Lemnitzer 1994).

It has been attempted to keep as close as possible to the conventions. However, some deviations were unavoidable. This concerns:

a. The extension of value sets for some attributes
b. The addition of some minor classes, described in a separate section (see Add on classes)
c. The additon or deletion of an attribute

We will try to justify the changes, or mark them as language-specific. However, some features will be topics for further discussion.

5.2.1 Nouns (N)

5.2.1.1 Lexicon

Attribute	Value	Example	Code
Type	common	Buch	c
	proper	Peter	p
Gender	masculine	Mann	m
	feminine	Frau	f
	neuter	Kind	n
Number	singular	Mann	s
	plural	Frauen	p
Case	nominative	Kind	n
	genitive	Kindes	g
	dative	Kinde	d
	accusative	Kind	a

5.2.1.2 Corpus

Tag	Regular expression	Definition
NCMSN	Ncmsn	Common noun, masc. sing., nominative
NCMSG	Ncmsg	Common noun, masc. sing., genitive
NCMSD	Ncmsd	Common noun, masc. sing., dative

Note:

Adding participles here would imply the addition of adjective features. Morphologically at least, participles behave like adjectives. A good - but not very elegant - solution would therefore be to handle participles as a type of adjective.

Secondly there are ambigous cases, e.g.

Er ist ger"uhrt.

where ger"uhrt is a participle, but might be tagged either as a verb or an adjective, depending on the context. This would be violating the assumption for applicativeness. The best solution at hand is to treat these forms as ambiguous with respect to membership in a word class (adjective and verb, respectively). However, this is a mixture of morphosyntactic with distributional criteria, and therefore unsatisfactory.

5.2.3 Adjectives (A)

5.2.3.1. Lexicon

Attribute	Value	Example	Code	
Type	qualificat.	gut	f	
	ordinal	zweites	o	
	cardinal	zwei	c	this value has been added
	possessive	mein	s	
	part1	lachende	1	this value has been added
	part2	gesungene	2	this value has been added
Degree	positive	gut	p	
	comparative	besser	c	
	superlative	beste	s	
Gender	masculine	guter	m	
	feminine	gute	f	
	neuter	gutes	n	
Number	singular	guter	s	
	plural	gute	p	
Case	nominative	guter	n	
	genitive	guten	g	
	dative	guten	d	
	accusative	guten	a	

Notes

a. We decided to include cardinal as well as ordinal numbers. Therefore there is no special class for numerals.

b. Although we have doubts concerning the "possessive adjectives" and would prefer to add the form

(Der Ball ist) mein

and

das ist meins

to the possessive Determiner or Pronouns because 'mein' originally is a possessive pronoun, we recognize that the present definition of these categories does not allow the addition of the value 'predicative'. This treatment is therefore a compromise.

c. German adjectives can be used in an attributive or a predicative mode. Predicative adjectives are not marked for gender, case or number with the exception of possessive and ordinal adjectives.

d. It would be necessary to specify the inflection type. The inflection type reflects the place of an adjective in an NP (following a determiner, an article, or none of these). Values are strong, mixed, and weak. However, we have left this feature in this generic version.

e. part1 refers to adjectives that are derived from present participles.
part2 refers to adjectives that are derived from past participles.

5.2.5. Determiners (D)

5.2.5.1 Lexicon

Attribute	Value	Example	Code
Type	demonstrat.	dieser	d
	indefinite	kein	i
	possessive	mein	s
	interrog.	welche	t
Person	first	mein	1
	second	dein	2
	third	sein	3
Gender	masculine	dieser	m
	feminine	diese	f
	neutre	dieses	n
Number	singular	dieser	s
	plural	diese	p
Case	nominative	dieser	n
	genitive	dieses	g
	dative	diesem	d
	accusative	diesen	a
Possessor	-	-	-

Note:

We included "person" as a feature in the lexical list, but we doubt whether this treatment is useful, at least seen from a German point of view. We prefer to treat the six possessive determiners which are derived from the personal pronouns as different lexemes.

Otherwise, the feature "Number" would have to be specified twice. First, to mark the proper attributes of the basic pronoun (e.g. 1. person plural for "unser") and second to mark the features of

agreement with the head of the NP ("unser Leben" vs. "unsere Kinder").

Furthermore, the person information is of semantic character for the possessive determiner, in contrast to the underlying personal pronoun, where the person information is also a feature of agreement with the verb or VP of a sentence.

The attribute 'possessor' is not grammatically relevant.

5.2.5.2 Corpus

Tag	Regular expression	Definition
DDMSN	Dd-msn-	Dem. determiner, masc., sing., nominative

Note:

We deliberately treat the Articles as an extra class, but related to the Determiners. The syntactic behaviour of Articles and Determiners in NPs is different, as can be seen by the adjective in the following examples:

```
      Ein kleines Haus
      Welches kleine Haus ?
```

This difference supports our attitude towards separating articles and determiners generally.

5.2.6 Articles (T)

5.2.6.1 Lexicon

5.2.8 Adpositions (S)

5.2.8.1 Lexicon

Attribute	Value	Example	Code	
Type	pre	an	p	
	post	wegen	t	this value has been added
	circum	von - an	c	this value has been added
	part1	von	a	this value has been added
	part2	an	z	this value has been added
Formation	clitic	ans	c	
	simple	an	s	

In German, most prepositions precede the NP. However, there is a good deal of them which follow the NP ("entlang") or enclose it ("von" NP "an"). This behaviour is unpredictable and must therefore be marked lexically. This is done by increasing the values of the "Type" attribute. This extension can be considered as language specific, as long as there is no evidence from other languages which supports this distinction. For practical reasons of text segmentation, the two parts of a circumposition have to be distinguished by different tags.

The attribute "formation" allows us to deal with clitic contraction of

preposition and article of the following NP ("zum", "ans")

5.2.8.2 Corpus

Tag	Regular expression	Definition
SPS	Sps	pre-position, simple
STS	Sts	post-position, simple
SPC	Spc	pre-position, clitic
SC	Sas	circumposition, partI, simple
SC	Szs	circumposition, partII, simple

5.2.8.3 Combinations

Lexique	Corpus	Example
Sps	SPS	an
Sts	STS	wegen
Spc	SPC	ans
Sas	SC	von
Szs	SC	an

5.2.9. Conjunctions (C)

5.2.9.1 Lexicon

Attribute	Value	Example	Code	
Type	coordinat.	oder	c	
	subordinat.	als	s	
	compar	als	v	this value has been added
	infinitive	um	i	this value has been added
	part1	entweder	a	this value has been added
	part2	oder	z	this value has been added

```
=========== ========== ==========    ====
```

Comparative conjunctions are restricted to constitutents as arguments. Subordinate conjunctions introducing an infinite clause lead to an infinite verb form in sentence final position. The infinitive particle may be incorporated, as in "wegzugehen". These morphosyntactic features lead to an extension of the feature-Type values, which may be considered as language specific.

There are also a few complex conjunctions which appear at the beginning of both phrases which are conjoined by it ("entweder - oder"). This feature has to be marked lexically, again by increasing the values of the "Type" attribute. For practical reason of text segmentation, the two parts of a complex conjunction have to be distinguished by different tags.

5.2.9.2 Corpus

Tag	Regular expression	Definition
CC	Cc	Cooordinative cunjunction
CS	Cs	Subordinative cunjunction
CI	Ci	Subord. conjunctions introd. an infinit. clause
CV	Cv	Comparative Conjunction
CA	Ca	Conjunction Part I
CZ	Cz	Conjunction Part II

5.2.9.3 Combinations

Lexique	Corpus	Example
Cc	CC	aber
Cs	CS	als
Ci	CI	um
Cv	CV	als

5.2.10 Numerals (M)

We do not support the class "Numerals". Possible elements of this class will be treated as nouns, adjectives, or adverbs.

5.2.11 Interjection (I)

5.2.11.1 Lexicon

Tag	Example
I	oh

5.2.11.2 Corpus

Tag	Regular expression	Definition
I	I	Interjection

5.2.11.3 Combinations

Lexique	Corpus	Example
I	I	oh

5.2.12 Add on classes

5.2.12.1 Particle (Q)

5.2.12.1.1 Lexicon

Attribute	Value	Example	Code
Type	infinitive	zu	i
	superlative	am	s
	verbal pref.	hinzu	v

5.2.12.1.2 Corpus

Tag	Regular expression	Definition
QS	Qs	superlative particle
QI	Qi	infinitive particle
QV	Qv	verbal prefix

Superlative particles precede the superlative form of adjectives, if used predicatively (er ist am gr"o"sten), and adverbs (applies also to Dutch).

Infinitive particles are found in each of the Germanic languages to be described (Danish, Dutch, English, German). This should be accounted for somewhere in the generic set of classes.

Verbal prefixes are a particular German (and Dutch) phenomenon and can be considered to be language specific.

5.2.12.1.3 Combinations

Lexique	Corpus	Example
Qi	QI	zu
Qs	QS	am
Qv	QV	hinzu

5.2.12.2 Punctuation (F)

5.2.12.2.1 Corpus

Tag	Regular expression	Definition
FE	Fe	sentence final
FI	Fi	sentence internal
FA	Fa	Quot mark / parenthesis initial
FZ	Fz	Quot mark / parenthesis final
FB	Fb	Hyphen, underscore, dash

The use of Tags for punctuation sign is obvious for the stochastic modelling of utterances. However, it is not clear whether they should be treated lexically. Therefore, we can describe our corpus tags, but not a lexical treatment of these units.

5.2.12.3 Abbreviations (Y)

5.2.12.3.1 Lexicon

Tag	Example
Y	bzw.

5.2.12.3.2 Corpus

Lexical abbreviations do not have a particular corresponding Corpus Tag, but are tagged according to the morphosyntactic behaviour of the form written out in full.

5.2.12.3.3 Combinations

Lexique	Corpus	Example
Y	RG	bzw.
Y	NCFSN	AG

5.2.12.4 Others (X)

Other particular corpus tags can correspond to the common class of Residual.

5.2.12.4.1 Corpus

Tag	Regular expression	Definition
SYM	X	Symbols (%, ’ etc.)
EQ	X	Formulae (5x + 3y)

5.3 Application to Spanish

The application of the MULTEXT morphosyntactic enconding for lexical descriptions and corpus tags to Spanish has been performed by the Spanish group (Bel and Aguilar 1994), and has been revised during phase B.

The proposed set of TAGS is not definitive. As repeteadly mentioned, we understand that this set will have to be refined depending on the results of application. These tags are the result of a comparison of two tagset sources:

a. information supplied by the tool SAC (a corpus analysis tool which includes a PoS rule based tagger and a lemmatizer) in form of attribute-value pairs.

b. tagsets proposed by the CRATER project.

Therefore these tags have to be taken as a starting point for refinement.

5.3.1 Nouns (N)

5.3.1.1 Lexicon

Attribute	Value	Example	Code
Type	common	libro	c
	proper	Juan	p
Gender	masculine	hombre	m
	feminine	mujer	f
Number	singular	hombre	s
	plural	mujeres	p
Case	///	///	-

5.3.1.2 Corpus TAGS: comments

Crater tags for nouns also include semantic information such as

"A"(anthroponymous) or "T"(toponymous) for proper nouns, aswell as "LOC"(ative), "MEA(sure)", etc. for common nouns. We will drop these values in order to get our proposal which intends to be like the one recommended in EAG-L1.

5.3.1.3 Combinations

Lexique	Corpus	Example
Ncms-	NCMS	hombre
Ncmp-	NCMP	hombres
Ncfs-	NCFS	mujer
Ncfp-	NCFP	mujeres
Npms-	NPMS	Juan
Npmp-	NPMP	Paris
Npfs-	NPFS	Ana

	second	eres	2
	third	es	3
Number	singular	viene	s
	plural	venimos	p
Gender	masculine	cantado	m
	feminine	cantada	f
Clitic	both	darselo	t
	accusative	darlo	a
	dative	darle	d

5.3.2.2 Corpus TAGS: comments

a. CRATER tags as well as our inhouse tags classify verb types into: main/ser/estar/haber/modal. "Ser", "estar", "haber" (normally considered auxiliaries) are more informative with respect to the

different constructions such as: perfect tenses, active/pasive distinctions and the disambiguation between adjectives and past participles.

Following French suggestion we could pass this information into a language specific attribute as Lexical Class.

Attribute	Value	Example	Code	
Lex. class	ser	ser	s	obviously
	estar	estar	e	language-specific
	haber	haber	h

5.3.4 Pronouns (P)

5.3.4.1 Lexicon

```
============ =========== =========== ====
Attribute    Value       Example     Code
============ =========== =========== ====
Type         personal    yo            p
             demonstrat. este          d
             indefinite  alguno        i
             possessive  (el) tuyo     s
```

	interrog.	que’	t
	relative	que	r
	reflexive	se	x
Person	first	yo	1
	second	tu’	2
	third	e’l	3
Gender	masculine	esto, el	m
	feminine	esta, ella	f
Number	singular	alguno	s
	plural	algunos	p
Case	nominative	el	n
	dative	le	d
	accusative	lo	a
	oblique	mi’,conmigo	o
Possessor	singular	mi’o	s
	plural	nuestro	p

5.3.4.2. Corpus TAGS: comments

a. CRATER TAGs make a distinction when proximal or remote deixis exists. We do not consider these values.

b. "se", which can be both dative and accusative depending on the existence of an ’external’ accusative:

Ella se lava (She washes herself)
Ella se lava las manos (She washes her hands)

There is also an oblique reflexive pronoun "si’".

TAGs would be:

Px3..-a	PX3SA	se
Px3..-d	PX3SO	se
Px3.s-o	PX3SO	si’

c. Relative pronouns are a good example of rearranging of linguistic information when comparing with French. For example, due to in Spanish there exists a relative pronoun which is also a possessive one (cuyo, cuya, cuyos, cuyas, eng. "whose") possessor values have been marked.

5.4 Application to French

In this section the proposed encoding is applied to French (Veronis et al. 1994).

5.4.1 Nouns (N)

5.4.1.1 Lexicon

Attribute	Value	Example	Code
Type	common	livre	c
	proper	Jean	p
Gender	masculine	homme	m
	feminine	femme	f
Number	singular	hommes	s
	plural	femmes	p
Case	///	///	-

5.4.1.2 Corpus

Tag	Regular expression	Definition
NCMS	Ncms-	Common noun, masc. sing.
NCMP	Ncmp-	Common noun, masc. plur.
NCFS	Ncfs-	Common noun, fem. sing.
NCFP	Ncfp-	Common noun, fem. plur.
NPMS	Npms-	Proper noun, masc. sing.
NPMP	Npmp-	Proper noun, masc. plur.
NPFS	Npfs-	Proper noun, fem. sing.
NPFP	Npfp-	Proper noun, fem. plur.

5.4.1.3 Combinations

Lexique	Corpus	Example
Ncms-	NCMS	homme
Ncmp-	NCMP	hommes

Ncfs-	NCFS	femme
Ncfp-	NCFP	femmes
Npms-	NPMS	Jean
Npmp-	NPMP	Pays-bas
Npfs-	NPFS	Anne
Npfp-	NPFP	Pyrenees

Note

It is not clear that all proper nouns should receive gender and number information. In addition, even if this information exists, it might be difficult to find it automatically in corpora for unknown proper nouns. We must experiment to see if a single tag NP would be better.

5.4.2 Verbs (V)

5.4.2.1 Lexicon

Attribute	Value	Example	Code
Type	main	partir	m
	auxiliary	avoir	a
Mood/Vform	indicative	viens	i
	subjunctive	vienne	s
	imperative	viens	m
	conditional	viendrais	c
	infinitive	venir	n
	participle	venu	p
Tense	present	viens	p
	imperfect	venais	i
	future	viendrai	f
	past	vins	s
Person	first	suis	1
	second	es	2
	third	est	3
Number	singular	viens	s
	plural	venons	p

Gender	masculine	venu	m
	feminine	venue	f
Clitics	///	///	-

Notes

a. Conditional

Conditional is often considered as a tense rather than a mood. Encoding decision may change on this.

b. Auxiliaries
It is possible that we need to discriminate between "avoir" and "eˆtre" auxiliaries. In that case, we could add a Lexical Class attribute:

Attribute	Value	Example	Code
Lex. class	eˆtre	eˆtre	e
	avoir	avoir	a

Note : obviously language-specific

c. Past participle
We decided to encode the past participle of the auxiliary verb "eˆtre", the copulative verbs (e.g. "sembler") and impersonal verbs (e.g."falloir"), which do not agree in gender, with the value not applicable (-) :

e'te' : Va---ps--, semble' : Vm---ps--

5.4.2.2 Corpus

Tag	Regular expression	Definition

5.4.3 Adjectives (A)

5.4.3.1 Lexicon

Attribute	Value	Example	Code
Type	qualificat.	bon	f
	ordinal	deuxieˆme	o
	cardinal	deux	c
	indefinite	quelconque	i
	possessive	mien	s
Degree	positive	bon	p
	comparative	meilleur	c
Gender	masculine	bon	m
	feminine	bonne	f
Number	singular	bon	s
	plural	bons	p
Case	///	///	-

Notes

a. Degree
We encode Degree for compatibility with other languages, but the distinction positive/comparative applies only to two adjectives in French: "bon" and "mauvais". All other adjectives form their comparatives with "plus" + adjective (e.g., "plus grand"). Superlative is also a compound form ("le" + comparative, e.g. "le plus grand").

b. Possessor
We could add attributes for person and number of possessor.

c. Cardinal
The use of this value in french is still being considered as it seems perfectly redundant with the category numeral.

5.4.4 Pronouns (P)

5.4.4.1 Lexicon

Attribute	Value	Example	Code
Type	personal	je	p
	demonstrat.	celui	d
	indefinite	certain	i
	possessive	le_mien	s
	interrog.	lequel	t
	relative	quel	r
Person	first	je	1
	second	tu	2
	third	il	3
Gender	masculine	cet,il	m

	feminine	cette,elle	f
	neutre	ce	n
Number	singular	certain	s
	plural	certains	p
Case	nominative	il	n
	object	le, lui	j
	oblique	moi	o
Possessor	singular	mon	s
	plural	nos	p

Notes

a. Possessive

Possessive pronouns are compound forms only ("le mien"). The form "mien" is an adjective (see note supra).

b. Case

The case system proposed by EAGLES (nominative, accusative, dative, oblique, etc.) does not map readily to French personal pronouns. The usual typology is the following:

subject	je, tu, il, elle, nous, vous, ils, elles
object	me, te, le, la, lui, se, nous, vous, les, leur, se
other	moi, toi, lui, elle, soi, nous, vous, eux, elles, soi

The category "other" corresponds to reinforcement of subject or object ("Moi, je le dis"), attribute ("C'est moi"), etc.

We could use the following mapping:

```
Nominative  --> subject
Accusative  --> direct object
Dative      --> indirect object
Oblique     --> other
```

However, this solution splits "object" in "direct" and "indirect", and

this distintion is valid only for the 3rd person pronouns in French (direct: le, la, les; indirect: lui, leur). Encoding this distinction would duplicate all other forms (direct:me, te, etc.; indirect: me, te, etc.).

We have therefore added one value to the case system proposed: the value "Object".

c. New values exclamative, reflexive, reciprocal

The addition of those new values for the attribute type has not yet been considered in French. It is clear that the value "exclamative" would be more useful for the Determiner category (where it is merged with the interrogative value). As for reflexive and reciprocal values, they may be redundant with the codes using the case-value "j" (object), applied to personal pronouns.

d. Agglutination

The presence of disjuncted lexical units among pronouns has led to their lexicalisation for the sake of consistency of some paradigms : for instance the paradigm "auquel", "auxquels" and "auxquelles" is completed with the unit _laquelle", which is not completely satisfactory.

5.4.6 Adverbs (R)

5.4.6.1 Lexicon

Attribute	Value	Example	Code
Type	general	fortement	g
	particle	ne, pas	p
Degree	positive	fortement	p
	comparative	davantage	c
	negative	ne, pas	n

Note

We encode degree for compatibility with other languages, but as for adjectives, the comparative feature is not very productive in French. It applies only to "beaucoup" (comp.= "davantage"), "bien" (comp.= "mieux"), "mal" (comp.= "pis") and "peu" (comp. = "moins"). The comparative for other adverbs is marked by "plus" + adverb (e.g. "plus fortement"). The superlative is usually marked by "le" + comparative (e.g. le plus fortement).

5.4.6.2 Corpus

Tag	Regular expression	Definition
R	Rg.-	General adverb
R-NE	Rpn	ne
R-PAS	Rpn	pas

Note

It seems necessary in French to distinguish the two parts of the negation ("ne ... pas"), because they play an important role in disambiguation. However, this violates the applicative principle (the categories in the corpus should be broader than the categories in the lexicon). Here the same lexical category (Rpn) would split in two corpus tags (R-NE, R-PAS). As a result, the regular expression Rpn cannot be used to define the corpus tags unambiguously.

We could add an attribute "Lexical Class" to discriminate between the two particles, as, if needed, for the distinction between the "eˆtre" and "avoir" auxiliaries (see note supra).

Attribute	Value	Example	Code
Lex. class	ne	ne, n’	n
	pas	pas, plus	p

However, the auxiliary distinction applied to many languages (English: be/have; Italian: essere/avere, etc.), whereas the negation problem seems specific to French. It seems therefore heavy to impose an attribute "Lexical Class" for all languages in the Adverb category.

Another point of view would be to consider that, in fact, some lexical subcategorization will be needed for one category or another in each language, and add a "Lexical Class" attribute to all the part-of-speech categories in a systematic way.

5.4.6.3 Combinations

Lexique	Corpus	Example
Rgp	R	beaucoup
Rgc	R	davantage
Rpn	R-NE	ne
Rpn	R-PAS	pas, plus

Attribute	Value	Example	Code
Type	cardinal	deux	c
Gender	masculine	un	m
	feminine	une	f
Number	singular	un	s
	plural	deux	p
Case	///	///	-

Note:

Ordinals are simple adjectives in French. They can never be determiners (e.g. *premie're fois e'tait la bonne).

Traditionnal grammars usually distinguish un/article and un/numeral. However, it is very difficult to find linguistic tests that enable to discriminate between the two.
cf. J'ai vu un chat (article)
J'ai vu un chat et deux chiens (numeral?)

We will not keep this distinction in the corpus tags.

Only un/une have a gender. All other numerals are invariant in gender. We will encode gender as not applicable rather than introduce a systematic homography.

5.4.9.2 Corpus

Tag	Regular expression	Definition
M	Mc-s-	Cardinal numeral, sing.
M	Mc-p-	Cardinal numeral, plur.

5.4.9.3 Combinations

Lexique	Corpus	Example
Mcms-	DMS	un
Mcfs-	DFS	une
Mc-s-	M	zero
Mc-p-	M	deux, trois

5.4.10 Interjection (I)

5.4.10.1 Lexicon

Tag	Example
I	eh

5.4.10.2 Corpus

Tag	Regular expression	Definition
I	I	Interjection

5.4.10.3 Combinations

Lexique	Corpus	Example
I	I	eh

5.4.11 Unique membership class (U)

None.

5.4.12 Residual (X)

5.4.12.1 Lexicon

Tag	c	Example
X	c	symbols, etc.

5.4.12.2 Corpus

Tag	Regular expression	Definition
X	X	Residual

5.4.12.3 Combinations

Lexique	Corpus	Example
X	X	symbols, etc.

======= ==

5.5 Application to English

The application to English has been carried out by the MULTEXT Group at ISSCO (ISSCO 1994). Note that this application has been carried out on the basis of the attributes and the values as presented in the preceding version of this deliverable (MULTEXT WP1.6 A2 version).

Notation:

Trailing place-holders have been omitted.

It should be borne in mind that the need for place-holders is an artefact of the linear representation of lexical descriptions. A number of extensions have been made to the various proposals circulated. It is not clear how language-specific they are, but they represent phenomena that are plausibly relevant for various text-processing tasks.

```
5.5.1 Nouns (N)
---------------

= ============== ============== =
P ATT            VAL            C
= ============== ============== =
1 Type           Common         c
                 Proper         p
- -------------- -------------- -
2 Number         Singular       s
                 Plural         p
- -------------- -------------- -
3 Gender         Masculine      m
                 Feminine       f
                 Neuter         n
= ============== ============== =

Notes:

Case is not relevant for English.

Gender is probably unnecessary for most purposes. We can assume it may
be of interest in constructions with pronouns.  Many nouns are (or may
be) unmarked for number: fish, sheep, aircraft.

Examples:
```

```
    Ncsn   house
    Ncpn   houses
    Npsn   Thames
    Nppn   Alps
    Ncpf   women
    Ncsm   man
    Nc=n   sheep
```

5.5.2 Verbs (V)

P	ATT	VAL	C	
1	Type	Main	v	
		Auxiliary	a	
		Modal	m	
2	Form	Indicative	i	Form, not Mood
		Imperative	m	
		Subjunctive	s	
		Base	b	base, not infinitive
		Past Prt	p	Past Prt, not participle
		Present Prt	g	Present Prt added (not gerund)
3	Tense	Present	s	
		Past	d	
4	Number	Singular	s	
		Plural	p	
5	Person	First	1	
		Second	2	
		Third	3	

Notes:
Voice is not lexical.

Attributes have been reordered to minimize sequence lengths (assuming the proposal about trailing "-"s) - Tense only applies to Finite verbs,

Number only to Present, and Person only to Singular. Modals have been included as a distinct subcategory.

Finiteness as an attribute is redundant - predictable from verb-form and past/present.

These tags do not attempt to represent distinctions found in the various compound verb-forms. These are composed of a sequence of auxiliary and non-finite verb as follows:

future	will/shall + base
conditional	would/should + base
passive	be + past participle
perfect	have + past participle
past perfect	have-past + past participle
present continuous	be + present participle
infinitive	to + base

So there is no "aspect" attribute or "future" value, for example.

Examples:

go	Vvm, Vvb, Vvs, Vvisp, Vviss1, Vviss2
goes	Vviss3
going	Vvg
gone	Vvp
went	Vvid
have	Vab, Vas, Vaip, Vaiss1, Vaiss2
has	Vaiss3
had	Vap Vaid
having	Vag
be	Vab, Vam
am	Vaiss1
are	Vaiss2, Vaisp
is	Vaiss3
was	Vaids1, Vaids3
were	Vaids2, Vaidp
been	Vap
being	Vag
will	Vmi
would	Vmi

5.5.3 Adjectives (A)

P	ATT	VAL	C	
1	Degree	Positive	p	
		Comparative	c	
		Superlative	s	
2	Position	Attributive	a	Position added
		Predicative	p	

Notes:

Gender, number and case irrelevant for English.

Attributive/predicative distinction reflects positional constraints - some adjectives ('mere', 'utter', etc.) only appear in prenominal position, while others ('awake', 'devoid', etc.) only appear in predicative position. Most can appear in either.

Since many English comparatives & superlatives are formed with more/most, "positive" cannot be interpreted as "neither comparative nor superlative". See "Adverbs".

Examples:

big	Ap
bigger	Ac
biggest	As
more peculiar	Dscn+Ap
most remarkable	Dssn+A
awake	App
mere	Apa

5.5.4 Pronoun (P)

=	=============	=============	=

P	ATT	VAL	C	
1	Pron.-Type	General	g	General added
		Demonstrative	d	
		Possessive	s	
		Personal	p	
		Reflexive	x	
2	WH	Not-WH	n	WH added
		Relative	r	
		Int	q	
3	Number	Singular	s	
		Plural	p	
4	Person	First	1	
		Second	2	
		Third	3	
5	Gender	Masculine	m	
		Feminine	f	
		Neuter	n	
6	Case	Nominative	n	
		Accusative	a	
7	Poss-Number	Singular	s	
		Plural	p	
8	Poss-Person	First	1	Poss-Person added
		Second	2	
		Third	3	
9	Poss-Gender	Masculine	m	Poss-Gender added
		Feminine	f	
		Neuter	n	

Notes:

"General" pronouns are those which are not personal, possessive, demonstrative or reflexive. The choice of these four categories is based on distributional facts, though at a rather high level of abstraction. They enter into anaphoric dependencies which are

signalled morphosyntactically and are therefore (in principle) more amenable to automatic detection. Most general pronouns do not, although they too sometimes encode number information.

"WH" attribute added to allow for combination of possessive and WH in "whose".

Examples:

Pgn	some, all, ...
Pgns	each, something, nothing, everything, -body, ...
Pgnp	both, ...
Pdns	this, that
Pdnp	these, those
Psn---s1	mine
Psn----2	yours
Psn---s3m	his
Psn---s3f	hers
Psn---s3n	its
Psn---p1	ours
Psn---p3	theirs
Psq	whose
Ppns1-n	I
Ppn-2	you
Ppns3mn	he
Ppns3fn	she
Ppns3n	it
Ppnp1-n	we
Ppnp3-n	they
Ppns1-a	me
Ppns3ma	him
Ppns3fa	her
Ppnp1-a	us
Ppnp3-a	them
Prns1	myself
Prns2	yourself
Prns3m	himself
Prns3f	herself
Prns3n	itself
Prnp1	ourselves
Prnp1	yourselves
Prnp1	themselves
Ppr	which
Ppq	which, what

5.5.5 Articles/Determiners (R)

P	ATT	VAL	C	
1	Type	Def-article	t	
		Indef-article	a	
		Demonstrative	d	
		Possessive	s	
		General	g	General added
2	WH	Not-WH	n	WH added
		Relative	r	
		Int/Excl	q	
3	Number	Singular	s	
		Plural	p	
4	Person	First	1	
		Second	2	
		Third	3	
5	Gender	Masculine	m	
		Feminine	f	
		Neuter	n	
6	Poss-Number	Singular	s	
		Plural	p	
7	Poss-Person	First	1	Poss-Person added
		Second	2	
		Third	3	
8	Poss-Gender	Masculine	m	Poss-Gender added
		Feminine	f	
		Neuter	n	

Notes:

Case not relevant to English.

Definite and indefinite articles represented as values of "Type". All of these have been marked as 3rd person. This is redundant, since determiners are all 3rd person, if anything.

Examples:

Rtn-3	the
Rans3	a/an
Rdns3-ns	this, that
Rdnp3-np	these, those
Rsn-3-s1	my
Rsn-3--2	your
Rsn-3-s3m	his
Rsn-3-s3f	her
Rsn-3-s3n	its
Rsn-3-p1	our
Rsn-3-p3	their
Rsr-3	whose
Rsq-3	whose
Rgr-3	which
Rgq-3	which, what,
Rgns3	each, ...
Rgnp3	all, both, certain, many, ...
Rgn-3	some, ...

5.5.6 Adverbs (D)

P	ATT	VAL	C	
1	Degree	Positive	p	
		Comparative	c	
		Superlative	s	
2	Function	Specifier	s	Function added
		Modifier	m	
3	WH	Yes	q	WH added
		No	n	

= ============== ============== =

Notes:

No distinction has been made between different types of "modifier" adverbs ("sentence-modifying", "VP-modifying", etc.), since their distributions overlap considerably.

Examples:

Dbsn	so, too, very, as
Dbsq	how
Dcsn	more
Dssn	most
Dbmn	quickly, soon, here, then, now
Dcmn	better, worse
Dsmn	best, worst
Dbmq	where, when, how, why

5.5.7 Adpositions (S)

P	ATT	VAL	C
1	Type	Preposition	e
		Postposition	o

Notes:

Postpositions are rare in English.

"possessive" 's and ' might be considered postpositions, especially if the alternative is to assign them to the unique membership class (where by definition they would be unrelated).

Examples:

Se	in, near, behind,...
So	notwithstanding, ago

5.5.8 Conjunctions (C)

P	ATT	VAL	C	
1	Type	Coordinating	c	
		Subordinating	s	
2	Comp-Type	Infinitive	i	Comp-Type added
		Finite	f	
3	Coord-Position	Initial	i	Coord-Position added
		Non-initial	n	

Notes:

Subordinating conjunctions are often identical to prepositions (before, after, since, ...).

"Comp-Type" encodes information about the complement of subordinating conjunctions. Present-participle complements have not been allowed for here; they consist of bare VPs and are often treated as nominal constructions, the words that introduce them (by, after, etc.) being classified as prepositions.

"Coord-Position" encodes the distinction between elements of a discontinuous coordination. "Initial" conjunctions are those that appear before the first conjunct, and "Non-initial" conjunctions are those that appear elsewhere. There is a dependency between initial and non-initial conjunctions ('both...and' but not 'either...and') which is not expressed in these attributes.

Examples:

```
Ccn  and, or, but
Cci  either, neither, both
Csi  for
Csf  that, because, ...
```

5.5.9 Numerals (M)

P	ATT	VAL	C
1	Type	Cardinal	c
		Ordinal	o

Notes:

"Function" depends on syntactic context.

These have not been subsumed under adjectives, pronouns, determiners, etc. because the internal structure of complex numerals is idiosyncratic.

Examples:

Mc	six
Mo	sixth

5.6 Application to Dutch

5.6.1 Multext morphology formalism

The main reason for having morphology is to facilitate maintenance of lexical lists, both during the project and afterwards. It follows that the rule formalism for morphology itself should not be a source of complexity. The designers of the Multext morphology tool have therefore decided to use fairly common, well-known methods, avoiding any adventurous modernism.

The tool has two parts: morphosyntax and morphographemics.

For morphosyntax, a user-friendly version of context-free grammar is used. The friendlyness comes with the possibility to annotate rules with features, and to set features to the same values through variables.

For morpho-graphemics, a version of two-level morphology is used.

The system can be used to generate a word list from an input word list, as well as to look words up in a given word list.

The full description and detail of the rule formalism are given in the report on the Multext morphology tool (Report nr. 2.3.1B) and the manuals accompanying the tool. Extensive exemplification can be found in the report on Multext morphology resources, Report nr. 5.3.1B.

5.6.2 Dutch word classes

The Dutch word classification used for Multext approximates as closely as possible the proposal in Deliverable A, section 1.6.1.

It can be summarized best in terms of (the relevant selection from) the types and attributes used in the actual Dutch description (Report 5.3.1B, section on Dutch).

There are 10 word class types:

```
V               : Vtype Vform  Person Number Tense
N               : Ntype Semgender Gender Number
```

```
A               : Inflected Degree
Adp             : AdpType
Det             : DetType Number Gender Defness
Pron            : PronType Number Defness Person Semgender Case
Adv             : Nil
Num             : Nil
Conj            : ConjType
Interj          : Nil

where:

Vtype           : Main Aux Copula Impersonal
Tense           : Pres Past
Person          : 1 2 3
Number          : Sg Pl
Vform           : Inf ImPart PerfPart Fin
Ntype           : Common Proper
Semgender       : M F N
Gender          : De Het none
Degree          : Pos Compar Super
Inflected       : 0 1
AdpType         : Post Pre
DetType         : Article Quantificational Possessive Demonstrative
Defness         : Def Indef
PronType        : Reciprocal Reflexive Personal Relative Demonstrative
                  Quantificational Interrogative
Case            : 1 4
ConjType        : Coord Subord
```

Dutch is not a morphologically rich language. A distinction that it makes which is different from most other Multext languages is that between ‘syntactic’ and ‘semantic’ gender. A good example is ‘meisje’ (girl). The syntactic gender is ‘het’ (‘het meisje’ *‘de meisje’) but the semantic gender is female (‘het meisje(i) dacht dat ze(i)/*hij(i)/??het een jongetje was’). It can be seen in the example that articles agree with their nouns in syntactic gender and that pronouns (usually) agree with their antecedents in semantic gender.

For the rest, the distinctions given differ from other languages mainly in what Dutch does not express.

The distinction between pronouns and determiners has been implemented as follows:

for any X that could be either a det or a pron:
if X distributes like NP, then X is a pronoun;
if X distributes like Det (i.e. NP-initial), then X is a determiner

It is hoped that this is a good starting point for tagging but this remains to be seen. As a consequence, a word like 'mijn' which is often called a pronoun is analysed as a determiner here.

Decisions like this one on function words can easily be changed; e.g. in the lexicon supplied for Dutch (Report nr. 5.4.1B), 59 words are classified as pronouns and 27 as determiners.
